٧.

None of the document D1-D9 discloses the method for the preparation of Morphine-6-glucuronide (M6G) claimed in claims 1-7. Therefore, the subject-matter of claims 1-7 meets the requirements of Art. 33(2) PCT.

The compounds(10), (11), (12), (14), (15), (16) claimed in claims 8-13 are known from the prior art documents D1-D9. However, their use in the synthetic route on file as claimed in claims 8-13, which are purpose-limited product claims, is not disclosed nor suggested in said prior art. It follows that the claimed matter 8-13 meets the requirements of Art. 33(2) and (3) PCT.

Document D2-D5 does not relate to the synthesis of M6G. Thus, they are not considered relevant for the evaluation of inventive step for the claimed matter 1-7.

Documents D1, D7, D8, D9 are relevant prior art documents. In particular, D1 is regarded as the closest prior art.

According to D1 (p. 10) "This invention uses D-glucurono-6,3-lactone which is converted to esters of tetra-O-acyl-ß-D-glucopyranuronates (2) (where the acyl group could include...pivalyl,...). The product could then be condensed directly in the presence of a catalyst such as trimethylsilyl triflate or a Lewis acid, with morphine or a derivative whereby the phenolic OH group is protected, e.g. as a ... pivalyl ... After condensation, protecting groups can be removed by hydrolysis or other selective cleavage."

Differently from D1, in the process on file the methyl $1(\beta),2,3,4$ -tetra-O-pivaloyl glucuronate is further reacted to obtain the methyl $1-\alpha,2$ -ethylorthopivalate-3,4-di-O-pivaloylglucuronate, prior the condensation with the 3-O-pivaloylmorphine.

Since D1 does not suggest modifying the method therein disclosed in a way to render

INTERNATIONAL PRELIMINARY International application No. PCT/GB99/01777 EXAMINATION REPORT - SEPARATE SHEET

obvious the process on file, the subject-matter of claims 1-7 is regarded as inventive over D1.

The synthesis of M6G according to D7-D9 does not proceed via the methyl $1(\beta),2,3,4$ -tetra-O-pivaloylglucuronate, rather via the methyl $1(\beta),2,3,4$ -tetra-O-acetyl glucuronate (D7, D9) or the methyl 1-deoxy-1- α -bromo,2,3,4-tri-O-acetyl glucuronate(D8). Thus, an inventive step for the claimed matter 1-7 over D7-D9 is acknowledged.

The invention provides a novel method for synthesising Morphine-6-Glucuronide (M6G) and intermediates therefor.

Synthesis of M6G from 3-acetylmorphine and methyl 2-α-bromo-3,4,5-tri-O-acetylglucuronate is described by Lacy, C., et al. (Tetrahedron Letters, 36 (22), (1995), 3949-3950).

Hidetoshi, Y. et al., (Chemical and Pharmaceutical Bulletin, JP, TOKYO, 16 (11), (1968), 2114-2119) describe synthesis of M6G by reaction of 3-acetyl-morphine with a bromo derivative of glucuronic acid to form a Methyl [3-acetylmorphin-6-yl-2,3,4-tri-0-acetyl-β-D-glucopyranosid] uronate intermediate which is subsequently hydrolysed to M6G.

WO 93/05057 discloses preparation of M6G by reaction of 3-acetyl morphine with methyl 1α -bromo, 1-deoxy, 2,3,4-tri-O-acetyl D glucopyranuronate and subsequently hydrolysing the resulting intermediate to M6G.

In order to synthesise M6G the major problem to overcome is to obtain the glycoside linkage with very high 6-selectivity since prior methods produce the α -anomer.

One method for obtaining high β -selectivity is to use trichloroimidate as the leaving group, as shown in WO 93/03051: Figure 1 (Salford Ultrafine Chemicals and Research Limited).

Claims

A method for the preferential synthesis of the β-anomer of M6G which 1. includes the step shown in Scheme 10:

2. Synthesis according to claim 1 which includes the step shown in Scheme 7:

Synthesis according to claim 1 or 2 which includes the step shown in Scheme 3.

wherein use of DMAP is optional.

 Synthesis according to any preceding claim which includes the step shown in scheme 8:

Scheme 8

 Synthesis according to any preceding claim which includes the step shown in Scheme 9:

Scheme 9

- Synthesis according to any preceding claim which includes a step to hydrolyse the protecting groups from compound 16.
- 7. Synthesis according to claim 6 in which the hydrolysis is as shown in Scheme 11:

Scheme 11

Morphine-6-Glucuronide Synthesis

The invention provides a novel method for synthesising M6G, and intermediates therefor.

In order to synthesise M6G the major problem to overcome is to obtain the glycoside linkage with very high β -selectivity since prior methods produce the α -anomer.

One method for obtaining high β -selectivity is to use trichloroimidate as the leaving group, as shown in WO 93/03051: Figure 1 (Salford Ultrafine Chemicals and Research Limited).

, 4

Orthoesters are simple to synthesise from their respective bromides¹. There is a reaction reported in the literature² between the glucuronate orthoester (2) and the sugar derivative (3) catalysed by lutidinium perchlorate³ (4) (Scheme 1).

Scheme 1

When this reaction was repeated with the t-butyl orthoacetate (5) and cyclohexanol (6 equivalents), the desired product (6) was isolated in 9% yield. Two other products also suggested that they were the desired product, but with the loss of one acetyl group, isolated in a combined yield of 43% (Scheme 2).

When 1.2 equivalents of 4-tert-butylcyclohexanol was used, the desired compound (7) was obtained in 1.7% yield. Other compounds obtained from the reaction also appeared to contain the desired peaks in the nmr, but after further examination proved to be the product of transorthoesterification (8) (Scheme 3).

Scheme 3

Reaction of orthoester (5) with protected morphine

Initially, 1.2 equivalents of 3-TBS protected morphine and the orthoester (5) were dissolved in chlorobenzene and half of the solvent was distilled off before 0.1 equivalents of lutidinium perchlorate (4) in chlorobenzene was added. The solvent was continuously distilled off while fresh solvent was added, and after 2.5 h another compound was formed with similar tlc properties to the protected morphine. Workup and chromatography gave a compound which corresponded to trans-orthoesterified material (9). None of the desired material was obtained (Scheme 4).

This product (9) was resubmitted to the reaction conditions (0.1 equivalents of lutidinium perchlorate and protected morphine in refluxing chlorobenzene) with no new products formed after 4h. Two further reactions were attempted using two equivalents of orthoester (5) and 0.2 equivalents of lutidinium perchlorate and 1 equivalent of orthoester (5) and 1.2 equivalents of lutidinium perchlorate, but both gave varying yields of orthoester (9).

We have concluded that a different, more bulky, alkyl group was needed on the orthoester to hinder attack there. Initially, the isopropyl group was examined. However, the initial reaction, perisobutyrylation, failed to give a compound which recrystallised from petrol, so the α and β anomers could not be separated. Therefore, attention focussed on the pivaloyl group.

The invention is further described with reference to the accompanying figure 2 which shows a summary of a reaction scheme according to the invention for synthesising M6G.

Synthesis of the Perpivalated Glucuronide

Synthesis of perpivalated glucuronide proved troublesome at first, giving a mixture of 3 and 4 non-pivalated material (scheme 5).

Scheme 5

A search through the literature

revealed that glucose can be perpivalated by heating the reaction to reflux for 3h. and then stirring it for 7 days.

When this reaction was repeated on ring-opened glucurono-3,6-lactone (Scheme 6), perpivalated product (10) was obtained by crystallisation of the crude product from MeOH (or EtOH) and water and drying the crystals by dissolving them in DCM, separating any water present, drying, and then evaporating the organic layer to give the product in 29-52% yield, a substantial improvement on previous yields for this step.

DMAP was added to aid perpivalation, although there has been no evidence to suggest that this is necessary. The variation in the yields quoted is probably due to the amount of MeOH left over from the first step. The high yield quoted (52%) was obtained by using 6 (instead of 5) equivalents of tBuCOCI. A slight

colouration of the final product proved no handicap in the next step, as after a silica plug and recrystallisation, pure white crystals were obtained.

Synthesis of the Orthoester (6)

Conversion of the perpivalated material (10) to the α -bromide (11) required gentle heating (to approxiamately 35° C) to dissolve the substrate in the reaction mixture. The reaction proceeded very cleanly by the analysis, showing a spot to spot conversion. Attempts to reduce the amount of HBr used to five equivalents led to incomplete conversion of the starting material, so 12 equivalents were used as before. The product was slowly crystallised from EtOH/water or MeOH/water to give long white crystals in a yield of 52-78%. High yields were always obtained when fresh HBr/AcOH was used. The crystals were dried by again dissolving them in dichloromethane, the water separated, and the organic layer dried and evaporated.

The orthoester (12) was obtained in 63-81% yield by stirring a 1:1 mixture of EtOH:collidine at 70° C (oil bath temperature) with the bromide (11) and 0.8 equivalents of EtaNBr (Scheme 7). The product can easily be crystallised from EtOH/water water or MeOH/water as white crystals, with a trace of collidine still present (detected by smell!) but which doesn't effect the next reaction. An interesting by-product from this reaction (obtained in about 10%) is the result of EtOH attacking the anomeric position to give the β -anomer (13) Again, the difficulty in drying the crystals meant that they were dissolved in petrol (40-60), the water separated, and the organic layer dried and evaporated.

Synthesis of 3-Pivalated morphine (14)

Selective deprotonation of the phenolic OH of morphine was achieved using NaH (surprisingly, the anion turns out to be soluble in THF) and trimethylacetyl chloride was added dropwise to give the desired product after recrystallisation from MeOH/water (Scheme 8). Again, the difficulty in drying the crystals meant that they were dissolved in dichloromethane, the water separated, and the organic layer dried and evaporated to give a white powder in 81% yield.

1.1 equivalents of trimethylacetyl chloride were used, but this led to some dipivalated morphine which proved difficult to recrystallise apart from monopivalated morphine (14) or the protected M6G (16). Thus, it would be advantagous in the future to use 1 equivalent of trimethylacetyl chloride.

Scheme 8

Synthesis of Lutidinium Perchlorate (15)

This was achieved by simply adding aqueous perchloric acid to an ether solution of lutidine (excess, as this remains in the Et_2O layer) (Scheme 9) and evaporating the water until crystals form, which were collected by filtration.

Scheme 9

The crystals are deliquescent and thus need to be dried under high vacuum prior to use.

8

Other acid catalysts have been investigated in the coupling reaction below, but with no success. However, this compound has shown no tendencies to decompose, proving both thermal and shock stable, so shouldn't prove a problem on scale up.

Coupling of the orthoester (12) with 3-pivalated morphine (14)

Coupling the orthoester (12) to 1.1 equivalents of 3-pivalated morphine (14) was achieved by adding 0.1 equivalents of lutidinium perchlorate (15) every 15 min. until 1.2 equivalents had been added to the distilling chlorobenzene. The reaction was then stirred under reflux for a further 2h. to give a mixture of 3-pivalated morphine (14) protected M6G (16) and much less polar materials. Work-up and crude purification by chromatography gave protected M6G (16) and 3-pivalated morphine (14) which was purified by recrystallisation from MeOH/(water, small quantity) to give (16) in 29% yield (with no detectable quantity of α -anomer or trans-orthoesterified material from nmr analysis) (Scheme 10).

This yield is the greatest amount obtained from this reaction and further improvements might be possible. Lutidinium perchlorate (15)was added every 15 min. as a solid appeared to crystallise from the reaction mixture (presumably the 3-pivalated morphine perchlorate) and, if no more catalyst is added, the major product turned out to be the trans-orthoesterified material (similar to orthoester (9) in Scheme 14). If 1.2 equivalents of lutidinium perchlorate (15)was added directly to the reaction, only 6% of coupled material was obtained (presumably as all the 3-pivalated morphine had been removed from the reaction as the

perchlorate salt). The main problem with adding the catalyst, is its insolubility in chlorobenzene lower than approxiamately 100° C. If it is possible on a large scale to add lutidinium perchlorate (15) in chlorobenzene at 100° C, this may prove not only simpler to add the catalyst, but also lead to increasing yields. The reaction also needs to be refluxed for an additional 2 hours after all the lutidinium perchlorate (15) has been added, to cause the trans-orthoesterified material to rearrange to the desired material.

Global Deprotection of Protected M6G (16)

Heating protected M6G (16) in MeOH until it dissolves before adding the water (which causes it to crystallise from the reaction mixture) and Ca(OH)₂ seems to be the mildest way of performing this reaction. After stirring for 3 days, the reaction gave, by tlc analysis, M6G (17) and morphine (Scheme 11).

The reaction was quite slow due to the insolubility of Ca(OH)₂ in water, but when the reaction is deemed to have finished by tlc analysis, 6.5 equivalents of sulfuric acid were added or until the reaction reached pH 4. The CaSO₄ so formed was filtered off and the trimethylacetic acid also formed was removed by washing the filtrate with DCM. Evaporating the water proved the hardest part of this reaction due to excessive foaming. Some CaSO₄ remains in the filtrate and this was removed by adding MeOH to crystallise it out. The residue produced after all the water had been evaporated was purified by repeated washing with MeOH as M6G is virtually insoluble in MeOH while morphine is soluble in it. The morphine present in the crude residue probably arrived there due to the di-pivalated morphine passing through the coupling reaction and then being deprotected to morphine in this final step. Hopefully, by using strictly 1 equivalent of trimethylacetyl chloride, this should eliminate the di-pivalated morphine, thus make purification of M6G even simpler, and increasing the yield for the final step.

The invention is further described in detail below by way of example only.

Example 1

Methyl 1β,2,3,4-tetra-O-pivaloylglucuronate

Glucurono-6,3-lactone (147 g, 0.8 mol) was stirred as a suspension in methanol (1L, not dried) under nitrogen. A catalytic amount of sodium methoxide (147 mg, 2.6 mmol) was added to the suspension, and after 2 hours most of the suspension was still present. The reaction proceeded very slowly at room temperature, \sim 18°C, but noticeably increased in rate when the reaction was warmed, therefore, the reaction was gently warmed to \sim 25°C. After another hour of stirring, most of the suspension had dissolved to leave a clear yellow solution that was then evaporated. The residue was found to be a solid, which tended to foam under vacuum, which made total removal of all the methanol difficult.

Chloroform (400mL), followed by 6 equivalents of pyridine (400mL, 4.8mol) and a catalytic amount of *N,N*-dimethyl-4-aminopyridine (4 g) was then added to the residue that slowly dissolved in this mixture. The solution was stirred using a magnetic stirrer plate and flea, but the problems encountered in continuously stirring this reaction would make an overhead mechanical stirrer preferable at this stage. The reaction was then cooled to 0°C and 5 equivalents of trimethylacetyl chloride (500mL, 4 mol) was added gradually, not allowing the reaction to warm to a temperature above ~8°C. The yellow/orange solution became colourless on addition of the first portion of trimethylacetyl chloride, and after approximately half of the volume was added, a white precipitate was observed (pyr.HCl). After addition was complete, the reaction was stirred overnight at room temperature before being heated at reflux for 2 hours, during

11

which time the reaction turned black with the white precipitate still present. TIC analysis showed that the desired product had been produced (Rf 0.5, 1:1 Et₂O:petrol), but some mono-unprotected material remained (Rf 0.3 and 2.8, 1:1 Et₂O:petrol). The reaction was then allowed to cool to room temperature over 3 hours, then further cooled to 0°C before methanol was added gradually (this quenches the excess trimethylacetyl chloride to give methyl trimethylacetate. which is evaporated off with the solvent). The black solution was then poured into a 2L separating funnel, and washed with water (600 mL), 1M HCI (2 * 600 mL), water (600 mL), and saturated aqueous NaHCO₃ (2 * 600 mL). The organic layer was then dried with MgSO₄ and passed through approximately 5cm of silica on a sinter funnel (which removed a black baseline compound). The silica was washed with dichloromethane (100 mL) and the combined filtrates evaporated to leave a black viscous oil, which was re-dissolved in ethanol (~1L) and had water added until the solution turned turbid (~500mL). More ethanol was added until the turbid solution cleared, and the solution was left to crystallise overnight. The yellow crystals were dissolved in dichloromethane (300 mL) and any excess water removed by separation, the dichloromethane layer was then dried and evaporated.

The white powder (113.5 g, 26%) was then used in the next reaction.

Methyl 1-deoxy-1-α-bromo,2,3,4-tri-O-pivaloylglucuronate

Methyl 1(β),2,3,4-tetra-O-pivaloylglucuronate (108.5 g, 0.2 mol) was dissolved in glacial acetic acid (500 mL) (with the aid of some gentle heating) and placed in a bath of cold water. 12 equivalents of 33% HBr in acetic acid (500 mL, 2.9 mol) were then added at a rate required to prevent the acetic acid freezing without the reaction exotherming too greatly. After the addition was complete, the reaction was allowed to warm to room temperature. If any white solid (starting material) persisted, gentle warming was applied to the reaction until it dissolved and the reaction then allowed to cool and stir overnight. The orange/brown solution was then cautiously poured into dichloromethane (500 mL) / water (500 mL), the organic layer separated, washed with water (500 mL) and saturated NaHCO3 (500 mL) (with care to avoid too rapid an evolution of CO2). The organic layer was then dried (MgSO₄) and passed through approximately 2 cm of silica, the silica was washed with more dichloromethane (50 mL) and the combined filtrates evaporated (taking care to remove all the dichloromethane). The residue was then dissolved in EtOH (~400 mL) and water added until the reaction turned turbid. More ethanol was added until the solution just turned clear and the product allowed to crystallise overnight which were collected by filtration. The crystals were dissolved in dichloromethane and the organic layer separated from any water that remained, dried (MgSO₄), and evaporated.

The white powder (76 g, 72%) was then used in the next reaction.

Methyl 1α,2-ethylorthopivalate-3,4-di-O-pivaloylglucuronate

MeO₂C PivO PivO PivO PivO PivO PivO O OEt

Et_xNBr PivO PivO O OEt

Et₂NBr PivO

Methyl 1-deoxy-1- α -bromo,2,3,4-tri-O-pivaloylglucuronate (69 g, 0.13 mol) was dissolved in collidine (300 mL) (pre-dried by distilling onto activated 3Å sieves) and ethanol (300 mL) (pre-dried by distilling from NaOEt onto activated 3Å sieves). 0.8 equivalents of pre-dried tetraethylammonium bromide (22 g, 0.1 mol) was then added to the reaction, which was stirred at 60°C (oil-bath temperature 70°C) overnight. The reaction was then cooled and poured into dichloromethane (500 mL) / water (500 mL) and the organic layer separated, dried (MgSO₄), and evaporated. The collidine was removed by low-pressure distillation (total evaporation is not necessary), the residue dissolved in EtOH (~400mL), and water added until the product started to crystallise out. The white crystals were collected by filtration and dissolved in petrol. The organic layer was then separated from any water that remained, dried (MgSO₄), and evaporated.

The white powder (50g, 78%) was then used in the next reaction.

Morphine (12a, 42 mmol) was added portionwise to a THF (80 mL, Na dried) suspension of 1.05 equivalents of petrol washed NaH (60 % dispersion in oil. 1.768 g, 44 mmol) at 0° C. After stirring for 1h at room temperature, 1.1 equivalents of trimethylacetyl chloride (5.7 mL, 46 mmol) were added to the clear reaction mixture at 0° C and eventually a white solid precipitated from the reaction. After 1h., MeOH (10 mL) followed by saturated aqueous sodium bicarbonate (100 mL) were added to the reaction which was then extracted with Et₂O (2x200 mL). The combined extracts were washed with brine (200 mL), dried, and evaporated. The residue was recrystallised from MeOH/water and the crystals dissolved in dichloromethane and the organic layer separated from any water that remained, dried (MgSO₄), and evaporated.

The white powder (12.6 g, 81%) was then used in the next reaction.

Lutidinium Perchlorate

A 60% aqueous solution of perchloric acid (29 mL, 0.27 mol) was added to 1.1 equivalents of lutidine (34 mL, 0.29 mL) in Et₂O (250 mL) at 0° C. After stirring for 0.5h. at room temperature, the aqueous layer was separated and the water evaporated until a white solid crystallised from the water, the crystals filtered off and washed with Et₂O to give the product as a white crystalline solid (30 g, 54%). The product was dried under high vacuum prior to use.

Methyl 1β-6'-*O*-(3'-*O*-pivaloylmorphine)-2,3,4-tri-*O*-pivaloylglucuronate

A chlorobenzene (400 mL) (distilled from CaH2 onto activated 3Å sieves) solution of 1.1 equivalents of 3-O-pivaloyoloxymorphine (8.49 g, 23 mmol) and methyl 1α ,2-ethylorthopivalate-3,4-di-O-pivaloylglucuronate (10 g, 20 mmol) was heated to reflux to distil off approximately half of the solvent. 0.1 Equivalents of lutidinium perchlorate (415 mg, 2 mmol) was then added to the reaction that was still at reflux. The reaction was then stirred at reflux for 15 min with chlorobenzene continuously distilled off and fresh chlorobenzene added. After this time, a further 0.1 equivalents of lutidinium perchlorate (415 mg, 2 mmol) was then added to the reaction. This procedure was repeated every 15 min until 1.2 equivalents of lutidinium perchlorate (5.2 q. 25 mmol) had been added. The reaction was then stirred at reflux for 2 hours with chlorobenzene continuously distilled off and fresh chlorobenzene added. After this time, the reaction was allowed to cool and then poured into dichloromethane (500 mL) / water (500 mL), the organic layer separated, washed with saturated aqueous sodium bicarbonate (500 mL), dried, and evaporated. The residue, after some of the chlorobenzene had been removed under low pressure, was applied to the top of a silica column and eluted with diethyl ether to remove the non-polar by-products and then with 5% methanol in dichloromethane. The desired product was separated from 3-Piv-M by recrystallisation from MeOH/water to give a white crystalline powder (4.76 g, 29%).

Morphine-6-gluconoride

Methyl 1β-6'-O-(3'-O-pivalayloxymorphine)-2,3,4-tri-O-pivaloylglucuronate (3.06 g. 3.77 mmol) was dissolved in MeOH (60 mL) (with the help of some heating) and had water (7 mL) followed by 6.5 equivalents of calcium hydroxide (1.817 g. 24.5 mmol) added to it. The reaction was stirred for two days when water (60 mL) was added and the reaction stirred for a further day until the reaction was shown to be complete by tlc analysis (Rf 0.3, 45% nBuOH; 15% water; 20% acetone; 10% acetic acid; 10% of a 5% aqueous solution of ammonia), 6.5 equivalents of 0.25M aqueous sulphuric acid (98 mL, 24.5 mmol) were added (pH 4) and the reaction stirred for 1 hour. The reaction was then filtered to remove CaSO₄ and the solid washed with water (30 mL). The filtrate was then washed with DCM (2x100 mL), three quarters of the water evaporated and the same quantity of MeOH added. The white solid (mainly CaSO₄) was then filtered and the filtrate evaporated. The residue (1.56 g) had MeOH (100 mL) added and the white solid filtered and repeatedly washed with MeOH to give the desired compound (1.05 g, 60%) which could, according to the literature, be recrystallised from H₂O/MeOH (although this has not been performed on this material).

Claims

 A method for the preferential synthesis of the β-anomer of M6G which includes the step shown in Scheme 6:

wherein use of DMAP is optional.

2. Synthesis according to claim 1 which includes the step shown in Scheme 7:

3. Synthesis according to claim 1 or 2 which includes the step shown in scheme 8:

4. Synthesis according to any preceding claim which includes the step shown in Scheme

9:

Synthesis according to any preceding claim which includes the step shown in Scheme
 10:

- Synthesis according to claim 5 which includes a step to hydrolyse the protecting groups from compound 16.
- 7. Synthesis according to claim 6 in which the hydrolysis is as shown in Scheme 11:

Scheme 11

- A compound of formula (10) or derivative thereof for use in a method according to claim 1.
- A compound of formula (11) or (12) or a derivative thereof for use in a method according to claim 2.
- A compound of formula (14) or a derivative thereof for use in a method according to claim 3.
- A compound of formula (15) or a derivative thereof for use in a method according to claim 4.

WO 99/64430 PCT/GB99/01777

 A compound of formula (12), (14), (15) or (16) or a derivative thereof for use in a method according to claim 5.

 A compound of formula (16) or (17) or a derivative thereof for use in a method according to claim 7.

6. The figure of the drawings to be published with the abstract is Figure No. X as suggested by the applicant. Decause the applicant failed to suggest a figure.	the text has been estable	shed, according to Rule 38.2(b), by this Authori	ity as it appears in Box III. The applicant may, port, submit comments to this Authority.
X as suggested by the applicant. None of the figures. because the applicant falled to suggest a figure.			1
because the applicant failed to suggest a figure.	I	· ·	None of the figures.
because this figure better characterizes the invention.			. —
	because this figure bette	r characterizes the invention.	

Form PCT/ISA/210 (first sheet) (July 1998)

INTENATIONAL SEARCH REPORT

national Application No

A. CLASSIFICATION OF SUBJECT MATTER
IPC 6 C07H17/00 C07H9/04

7H9/04 C07H13/04

C07D489/02 C07D213/06

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols) IPC 6-C070-C07H

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

Category °	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No
